

WS2811

Signal line 256 Gray level 3 channel
Constant current LED drive IC

Feature

- Output port compression 12V.
- Built in stabilivolt, Only add a resistance to IC VDD feet when under 24V power supply.
- Gray level 256 can be adjusted and scan frequency not less than 400Hz/s.
- Built in signal reshaping circuit, after wave reshaping to the next driver, ensure wave-form distortion not accumulate.
- Built-in electric reset circuit and power lost reset circuit.
- Cascading port transmission signal by single line.
- Any two point the distance more than 10m transmission signal without any increase circuit.
- When the refresh rate is 30fps, low speed mode cascade number are not less than 512 points, high speed mode not less than 1024 points.
- Send data at speeds of up to 400 Kbps and 800 Kbps two patterns.

Applications

- LED decorative lighting.
- Indoor/outdoor LED video or irregular screen.

General description

The WS2811 is 3 output channels special for LED driver circuit. It internal include intelligent digital port data latch and signal reshaping amplification drive circuit. Also include a precision internal oscillator and a 12V voltage programmable constant current output drive. In the purpose of reduce power supply ripple, the 3 output channels designed to delay turn-on function.

IC use single NZR communication mode. After the chip power-on reset, the DIN port received data from controller, the first IC collect initial 24bit data then sent to the internal data latch, the other data which reshaping by the internal signal reshaping amplification circuit sent to the next cascade IC through the DO port. After transmission for each chip, the signal to reduce 24bit. IC adopt auto reshaping transmit technology, making the chip cascade number is not limited the signal transmission, only depend on the speed of signal transmission.

The data latch of IC depend on the received 24bit data produce different duty ratio signal at OTR, OUTG, OUTB port. All chip synchronous send the received data to each segment when the DIN port input a reset signal. It will receive new data again After the reset signal finished. Before a new reset signal received, the control signal of OTR, OUTG, OUTB port unchanged. IC sent PWM data that received justly to OTR, OUTG, OUTB port, after receive a low voltage reset signal the time retain over 50us. We offer two package SOP8 and DIP8.

PIN configuration

PIN function

NO.	Symbol	Function description
1	OUTR	Output of Red PWM control
2	OUTG	Output of Green PWM control
3	OUTB	Output of Blue PWM control
4	GND	Ground
5	DOUT	Data signal cascade output
6	DIN	Data signal input
7	SET	Set work mode of IC as low speed model(connect VDD) or high speed model(vacant)
8	VDD	Power supply voltage

Absolute Maximum Ratings

Prameter	Symbol	Ratings	Unit
Power supply voltage	V_{DD}	+6.0~+7.0	V
Output voltage	V_{OUT}	12	V
Input voltage	V_I	-0.5~VDD+0.5	V
Operation junction temperature	T_{opt}	-25~+85	°C
Storage temperature range	T_{stg}	-55~+150	°C

Note: If the voltage on the pins exceeds the maximum ratings may cause permanent damage to the device.

Signal line 256 Gray level 3 channel
Constant current LED drive IC

Typical application circuit:

1. power supply is 5V with 1 LED and constant current (18.5mA) driving

Fig 1

This driving mode use constant current output, the advantage of is the LED can retain luminance and colour temperature when the power supply lessen. We require, in order to prevent power spikes phenomenon and power reverse polarity, series a not more than 100ohm resistor at the po-wer supply pin(VDD). The capacitance 104 as bypass capacitor. To prevent the reflection and hot-swap protection, we suggest to connect a 33 ohm resistor at the data input or output port for impedance.

2. power supply is 12V with 3 LED and constant current(18.5mA) driving

Fig 2

The same as the front mode, it is also use constant current output. In this circuit, R1 is used as the IC internal LDO divider resistance and the value is 2.7K. The capacitance 104 as bypass capacitor. To prevent the reflection and hot-swap protection, we suggest to connect a 33ohm resistor at the data input or output port for impedance. At the OUTR port we should add a divider resistance RR. The value of RR can be derived by the following equation:

$$RR = \frac{12 - 3V_{LED R}}{18.5} K\Omega$$

$V_{LED R}$ is the red LED forward conduction voltage drop.

Signal line 256 Gray level 3 channel
Constant current LED drive IC

Applying the outside-enlarged transistor mode, the highest voltage value of VCC depends on the NPN transistor's V_{CE0} , generally 25V above. The current of each channel is set by resistance RR/RG/RB, computation formula is as follows:

$$I_R = \frac{V_{CC} - 3V_{LEDR} - V_{CE}}{R_R}$$

In above formula, I_R is the current of output end OUTR, RR is the value of red voltage-dividing resistor, VCC as the power supply voltage of LED(here is 12V), $V_{LED R}$ is the red LED forward conduction voltage drop, VCE as the saturated pipe pressure drop of transistor. Likewise, the current of OUTG and OUTB can be set.

Select 5K Ω as value of base resistance R_L , magnification of NPN transistor $\beta > 150$, connect circuit according to the method of Fig 3, the luminance data of MCU sends is opposite to actual luminance.

R1 is LDO voltage-dividing resistor inside IC ($R1=2.7K\Omega$), the capacitance 104 as bypass capacitors, input end and output end of IC are connected a resistance 33ohm in series respectively to provide hot-swap protection and resistance matching.

4.power supply 12V with 6 LED and constant voltage driving

Applying the outside-enlarged transistor mode, the highest voltage value of VCC depends on the NPN transistor's V_{CE0} , generally 25V above. The current of each channel is set by resistance RR/RG/RB, computation formula is as follows:

$$I_R = \frac{V_{CC} - 6V_{LED R} - V_{CE}}{RR}$$

In above formula, I_R is the current of output end OUTR, RR is the value of red voltage-dividing resistor, VCC as the power supply voltage of LED(here is 24V), $V_{LED R}$ is the red LED forward conduction voltage drop, VCE as the saturated pipe pressure drop of transistor. Likewise, the current of OUTG and OUTB can be set.

Select $5K\Omega$ as value of base resistance RL, magnification of NPN transistor $\beta > 150$, connect circuit according to the method of Fig 3, the luminance data of MCU sends is opposite to actual luminance.

R1 is LDO voltage-dividing resistor inside IC ($R1 = 6.8K\Omega$), the capacitance 104 as bypass capacitors, input end and output end of IC are connected a resistance 33ohm in series respectively to provide hot-swap protection and resistance matching.
